# **Ducker Documentation**

*Release 2.0.0*

**Jorge Maldonado Ventura**

**Apr 08, 2017**

# CONTENTS:

- 1 First Steps with Ducker** **1**
- 1.1 Purpose . . . . . 1
- 1.2 Install Ducker . . . . . 1
- 1.3 Use it . . . . . 1
  
- 2 Making advanced searches** **3**
  
- 3 Interactive mode** **5**
  
- 4 Autocompletion** **7**
  
- 5 Customization** **9**
- 5.1 Aliases . . . . . 9
- 5.2 Colors of the interactive mode . . . . . 9

## FIRST STEPS WITH DUCKER

### 1.1 Purpose

The purpose of Ducker is to provide a quick way to make internet searches using DuckDuckGo without getting out of the command-line interface. It is very useful for people using an operating system without GUI and for people who like using the terminal for everything.

### 1.2 Install Ducker

Ducker works with Python 3 in any operating system with Python. Install it running the following command:

```
pip install ducker
```

### 1.3 Use it

Once installed, you can use it with `duck` or `ducker` commands. Imagine that you are looking for cheap skateboards, you can make Ducker launch a search with the following command:

```
duck buy cheap skateboard
```

## MAKING ADVANCED SEARCHES

From Ducker you can do pretty much the same that you can do with DuckDuckGo. It has options to search for images, videos and websites, to filter results by date, by website... To check out every available option execute `duck -h`.

You can search for images of ducks executing `duck -i ducks` or the long form `duck --image-search ducks`. It's very intuitive.

You can also use [DuckDuckGo bangs](#) and other nice features of DuckDuckGo. Note that you must escape the exclamation mark (!) in Bash when using bangs. To go directly to the website of the first search result you can execute `ducker !freakspot.net` or `duck \\freakspot.net`. You can make this types of searches more comfortable to type using aliases for your shell (see [Customization](#)).

DuckDuckGo makes spell corrections sometimes. If you don't the spelling of your results be corrected, then use the `--exact` flag.

You can even filter results by date with the `-t` and `--time` options. You must specify the time limit: a (any time), d (past day), w (past week), m (past month). For instance, `ducker -t d cats` will get you the results from the past day related to cats.

If you just want to output the search results pages you can use the `--np` and `--noprompt` options, which will perform the search, output it in the terminal and exit. If you prefer to output it in JSON format, you can use the `--json` parameter.

## INTERACTIVE MODE

Ducker comes with a powerful interactive mode, that allows you to view the information about results and open them from it. It can also be used to show more or less results at will. You can even specify the proxy of your network, if you have one. If you find a bunch of useful results and you want to open them at the same time, you can. For example, execute `o 1 3 4`, if you want to open the results 1, 3 and 5. To check out every option inside the interactive mode, just type `?` and press `Enter`.

To launch the interactive mode, just execute Ducker without any arguments. You can also specify command-line options. Most options work both in interactive and in non-interactive mode.

If you don't like the appearance of the interactive mode, you can change it specifying the terminal colors using the option `--colors`. For more information about that check *Colors of the interactive mode*. Or if you don't like colors, you can use the option `--nocolors`.

DuckDuckGo makes spell corrections some times. If you don't want your spelling to be corrected by DuckDuckGo, then use the `--exact` flag.

## **AUTOCOMPLETION**

Docker comes with autocompletion files for Bash and for Fish. If you have any of those shells, you should get autocompletion support when you install Docker with pip. When you install Docker manually, you must copy the file `autocompletion/docker.bash` to `/etc/bash_completion.d/` if you use Bash, or copy the file `autocompletion/docker.fish` to `/etc/fish/functions` or to `~/.config/fish/functions` if you use Fish.

## CUSTOMIZATION

### 5.1 Aliases

If you use an option of Ducker very often, you should consider making a shortcut for it in your shell. In Bash-like shells, you can make aliases. Let's say we want to add an option to search for articles in Wikipedia; we can create a Bash alias for that.

```
alias wikipedia='ducker \!w'
```

After that, calling `wikipedia` in the shell will open the main page of wikipedia, and calling `wikipedia free software` would open the “Free software” article from wikipedia. Note that we're using [DuckDuckGo bangs](#) and that the exclamation mark (!) must be escaped in Bash. To make Bash remember your alias for your next sessions you must add it to your `.bashrc` file.

### 5.2 Colors of the interactive mode

Ducker allows you to customize the color scheme via a six-letter string, reminiscent of BSD LSCOLORS. The six letters represent the colors of:

- indices,
- titles,
- URLs,
- nothing (may probably be used in a later version),
- abstracts,
- and prompts

respectively. The six-letter string is passed in either as the argument to the `-colors` option.

We offer the following colors/styles:

| Letter | Color/Style                                       |
|--------|---|
| a      | black   |
| b      | red   |
| c      | green   |
| d      | yellow  |
| e      | blue  |
| f      | magenta   |
| g      | cyan  |
| h      | white   |
| i      | bright black                                      |
| j      | bright red  |
| k      | bright green                                      |
| l      | bright yellow                                     |
| m      | bright blue                                       |
| n      | bright magenta                                    |
| o      | bright cyan                                       |
| p      | bright white                                      |
| A-H    | bold version of the lowercase-letter color        |
| I-P    | bold version of the lowercase-letter bright color |
| x      | normal  |
| X      | bold  |
| y      | reverse video                                     |
| Y      | bold reverse video                                |

The default colors string is GKGlxxy, which stands for

- bold bright cyan indices
- bold bright green titles
- bright yellow URLs
- cyan metadata/publishing info
- normal abstracts
- reverse video prompts

Note that:

- Bright colors (implemented as x1b[90m - x1b[97m) may not be available in all color-capable terminal emulators;
- Some terminal emulators draw bold text in bright colors instead;
- Some terminal emulators only distinguish between bold and bright colors via a default-off switch.

Please consult the manual of your terminal emulator as well as [https://en.wikipedia.org/wiki/ANSI\\_escape\\_code](https://en.wikipedia.org/wiki/ANSI_escape_code) for details.
